Statistical Disclosure Control (SDC) or Statistical Disclosure Limitation (SDL) seeks to protect statistical data in such a way that they can be released without giving away confidential information that can be linked to specific individuals or entities.

Why is confidentiality protection important?

There are three main reasons:

1. **Principle** It is a fundamental principle for Official Statistics that the statistical records of individual persons, businesses or events used to produce Official Statistics are strictly confidential, and are to be used only for statistical purposes.
2. **Legal** Legislation places a legal obligation to protect individual business and personal data. Legal frameworks regulate what is allowed and what is not allowed with regard to publication of private information.
3. **Quality** Respondents need confidence in the preservation of the confidentiality of individual information.
4. **Ethical:** It is unethical to disclose information that can be linked to specific individuals or entities.

- ▶ Legal frameworks regulate what is allowed and what is not allowed with regard to publication of private information.
- ▶ Before sensitive statistical databases can be made available to universities for research, confidentiality must be guaranteed.
- ▶ Users of statistical outputs should be aware of the reasoning and methodology behind statistical disclosure control.

Different outputs require different approaches to SDC and different mixtures of tools.

- ▶ Macrodata (Tabular data)
- ▶ Microdata
- ▶ Dynamic databases
- ▶ Statistical analyses

Disclosure

A disclosure occurs when a person or an organisation recognises or learns something that they did not know already about another person or organisation, via released data.

Types of disclosure risk:

(1) Identity disclosure

Residency	Age	Sex	Occupation
Salzburg	50	Male	Professor

(2) Attribute disclosure

Group	Males	Females	Total
Football fans	22	0	22
Non Football fan	93	85	178
Total	115	85	200

SDC seeks to optimise the trade-off between the disclosure risk and the utility of the protected released data.

- ▶ Risk: the probability of a disclosure event occurring.
- ▶ Utility: the usefulness of the data for the intended purpose.
- ▶ The goal is to find a balance between risk and utility.

Risk-utility trade-off

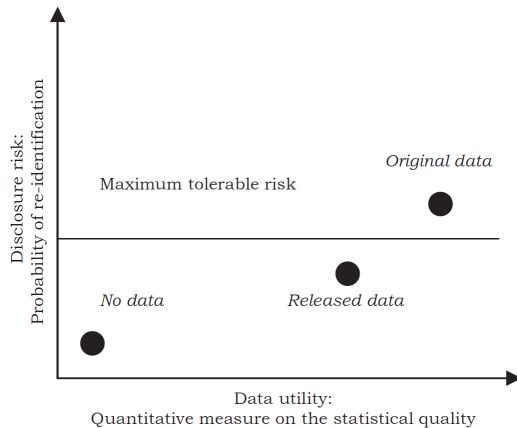

Figure 1: R-U confidentiality map (Duncan et al., 2001)

A unit is at risk of disclosure when it cannot be confused with several other units

- ▶ attacker scenarios and risk measures in more detail using examples

A data set is said to satisfy k-anonymity for $k > 1$ if, for each combination of values of quasi-identifiers (e.g. name, address, age, gender, etc.), at least k records exist in the data set sharing that combination.

Variables

1. Identifiers
2. Quasi-identifiers or key variables
3. Confidential outcome variables
4. Non-confidential outcome variables

Disclosure control methods

1. Masking original data
 - i. Non-perturbative masking.
 - ii. Perturbative masking.
2. Generating synthetic data

Packages for SDC - Microdata (Unit-level data)

[sdcMicro](#) can be used to anonymize data, i.e. to create anonymized files for public and scientific use. It implements a wide range of methods for anonymizing categorical and continuous (key) variables. The package also contains a graphical user interface, which is available by calling the function `sdcGUI`.

[simPop](#) using linear and robust regression methods, random forests (and many more methods) to simulate synthetic data from given complex data. It is also suitable to produce synthetic data when the data have hierarchical and cluster information (such as persons in households) as well as when the data had been collected with a complex sampling design. It makes use of parallel computing internally.

[synthpop](#) using regression tree methods to simulate synthetic data from given data. It is suitable to produce synthetic data when the data have no hierarchical and cluster information (such as households) as well as when the data does not collected with a complex sampling design.

Packages for SDC - Tabular data (Aggregated data)

[**sdcTable**](#) can be used to provide confidential (hierarchical) tabular data. It includes the HITAS and the HYPERCUBE technique and uses linear programming packages (Rglpk and lpSolveAPI) for solving (a large amount of) linear programs.

[**sdcSpatial**](#) can be used to smooth or/and suppress raster cells in a map. This is useful when plotting raster-based counts on a map. `sdcHierarchies` provides methods to generate, modify, import and convert nested hierarchies that are often used when defining inputs for statistical disclosure control methods.

[**SmallCountRounding**](#) can be used to protect frequency tables by rounding necessary inner cells so that cross-classifications to be published are safe.

[**GaussSuppression**](#) can be used to protect tables by suppression using the Gaussian elimination secondary suppression algorithm.

Non-perturbation methods

Non-perturbative masking does not rely on distortion of the original data but on partial suppressions or reductions of detail.

Table 3: Non-perturbative methods vs. data types.

Method	Continuous data	Categorical data
Sampling		X
Global recoding	X	X
Top and bottom coding	X	X
Local suppression		X
